Problem 1

Let R be a commutative domain, and let M be a free R-module with basis $X = \{e_1, \dots, e_k\}$, with $k \geq 2$. Prove that the element $e_1 \otimes e_2 + e_2 \otimes e_1$ cannot be written as simple tensor $m \otimes n$, for some $m, n \in M$.

Proof. Suppose, for the sake of contradiction, that there exist $m, n \in M$ such that $m \otimes n = e_1 \otimes e_2 + e_2 \otimes e_1$. Write $m = \sum_{i=1}^n r_i e_i$ and $n = \sum_{j=1}^n s_j e_j$ for some $r_i, s_j \in R$. Then

$$e_1 \otimes e_2 + e_2 \otimes e_1 = \left(\sum_{i=1}^n r_i e_i\right) \otimes \left(\sum_{j=1}^n s_j e_j\right) = \sum_{i,j} r_i s_j e_i \otimes e_j$$

As $M \otimes M$ is free with basis $\{e_i \otimes e_j\}_{i,j=1}^n$, it follows that $r_1s_2 = 1$, $r_2s_1 = 1$, and $r_is_j = 0$ for all $(i,j) \neq (1,2), (2,1)$. However, then $r_1s_1 = 0$ whence $r_1 = 0$ or $s_1 = 0$, contradicting $r_1, s_1 \in R^{\times}$.

Problem 2

Let R be a commutative ring (with 1) and $n, m \in \mathbb{N}$. Prove that there is an isomorphism of R-algebras $R^n \otimes R^m \simeq R^{nm}$. (Here by R^n we mean the direct sum $\underbrace{R \oplus \cdots \oplus R}_{r}$.)

Problem 3

(a) Let V be a finite-dimensional \mathbb{C} -vector space. Then V can be considered as a vector over \mathbb{R} (by restriction of scalars), and it holds $\dim_{\mathbb{R}} V = 2 \dim_{\mathbb{C}} V$. Prove that $V \otimes_{\mathbb{C}} V$ is not isomorphic to $V \otimes_{\mathbb{R}} V$ as \mathbb{R} -vector spaces, and compute their dimensions over \mathbb{R} .

Proof. Let $k = \dim_{\mathbb{C}} V$. Then $\dim_{\mathbb{R}} V = 2k$. As a \mathbb{C} -vector space, $\dim_{\mathbb{C}} V \otimes_{\mathbb{C}} V = (\dim_{\mathbb{C}} V)^2 = k^2$, whence by restricton of scalars $\dim_{\mathbb{R}} V \otimes_{\mathbb{C}} V = 2\dim_{\mathbb{C}} V \otimes_{\mathbb{C}} V = 2k^2$.

On the other hand $\dim_{\mathbb{R}} V \otimes_{\mathbb{R}} V = (\dim_{\mathbb{R}} V)^2 = (2k)^2 = 4k^2$. Hence

$$\dim_{\mathbb{R}} V \otimes_{\mathbb{C}} V = 2k^2 \neq 4k^2 = \dim_{\mathbb{R}} V \otimes_{\mathbb{R}} V$$

so $V \otimes_{\mathbb{C}} V$ and $V \otimes_{\mathbb{R}} V$ are not isomorphic as \mathbb{R} -vector spaces.

(b) Let R be an integral domain (commutative), and let K be its fraction field. Prove that there is an isomorphism of F-modules, $F \otimes_R F \simeq F \otimes_F F \simeq F$, where the F-module structure on $F \otimes_R F$ is given by extension of scalars (i.e. tensor product of Type I).

Problem 4

The purpose of this problem is to classify all 2-dimensional \mathbb{R} -algebras (where \mathbb{R} are the real numbers). That means, to classify (up to algebra isomorphism) those \mathbb{R} -algebras that are 2-dimensional \mathbb{R} vector spaces. Let A be a 2-dimensional \mathbb{R} -algebra (with 1).

- (a) Let $u \in A$ be any element that is \mathbb{R} -linearly independent from 1. Prove that
 - (i) u generates A as an \mathbb{R} -algebra. That is, the minimal \mathbb{R} -subalgebra of A containing u and 1 is A itself.
- (ii) The element u satisfies a quadratic equation $au^2 + bu + c = 0$, for some $a, b, c \in \mathbb{R}$ with $a \neq 0$. Conclude that A is necessarily commutative.

Proof. Noting that the subalgebra generated by u contains $\operatorname{span}_{\mathbb{R}}(\{1,u\})$ which has dimension 2 as an \mathbb{R} -vector space, it follows that the subalgebra generated by u is in fact A.

Since the subalgebra generated by u is A, it follows that there exist $a, b \in \mathbb{R}$ such that $u^2 = au + b1$, whence $u^2 - au - b = 0$. This implies the algebra A is commutative as multiplication is hence defined by the relations $u \cdot 1 = u = 1 \cdot u$ and $1 = 1 \cdot 1$, which are all commutative.

(b) Show that there exists some $v \in A$ which is \mathbb{R} -linearly independent from 1 and is such that $v^2 = -1$, or $v^2 = 1$, or $v^2 = 0$.

Proof.

- (c) Deduce from part (b) that A is isomorphic as an \mathbb{R} -algebra to one of the following: $\mathbb{R}[x]/(x^2+1)$, or $\mathbb{R}[x]/(x^2-1)$, or $\mathbb{R}[x]/(x^2)$.
- (d) Prove that the algebras $\mathbb{R}[x]/(x^2+1)$, $\mathbb{R}[x]/(x^2-1)$, and $\mathbb{R}[x]/(x^2)$ are pairwise non-isomorphic. Hint: This can be shown with almost no computation.

Problem 5

The purpose of this problem is to prove the following theorem: Let D be a finite dimensional division algebra over \mathbb{R} . Then D is isomorphic to \mathbb{R} , \mathbb{C} or \mathbb{H} (the quaternions). One way to proceed is to use the following steps:

(a) Let $\alpha \in D$ be an element \mathbb{R} -linearly independent from 1. Show that α satisfies a quadratic irreducible polynomial $p_{\alpha}(x) = x^2 + ax + b \in \mathbb{R}[x]$.

Proof. Since D is finite-dimensional over \mathbb{R} , there exists an $n \in \mathbb{N}$ such that the set $\{1, \alpha, \dots, \alpha^n\}$ is \mathbb{R} -linearly dependent. Hence α is algebraic over \mathbb{R} , so the set $I_{\alpha} = \{f(x) \in \mathbb{R}[x] : f(\alpha) = 0\}$.

As I_{α} is an ideal and $\mathbb{R}[x]$ is a PID, there exists a (without loss of generality) monic polynomial $p_{\alpha}(x) \in \mathbb{R}[x]$ such that $I_{\alpha} = (p_{\alpha})$. As α is algebraic, $p_{\alpha} = \neq 0$. Moreover, p_{α} is nonconstant by $p_{\alpha}(\alpha) = 0$. Hence, p_{α} is not a unit in $\mathbb{R}[x]$. If $f \in I_{\alpha} = (p_{\alpha})$ is irreducible, then in writing $f = gp_{\alpha}$ for some $g \in \mathbb{R}[x]$, irreducibility implies that $(f) = (p_{\alpha}) = I_{\alpha}$. Moreover, this implies that $\deg(f) = \deg(p_{\alpha})$, so p_{α} being monic implies that p_{α} is the unique irreducible monic element of I_{α} .

As $\alpha \notin \mathbb{R} \cdot 1$, $\deg(p_{\alpha}) \geq 2$. By the Fundamental Theorem of Algebra, it follows then that p_{α} must be quadratic, so there exist $a, b \in \mathbb{R}[x]$ such that $p_{\alpha}(x) = x^2 + ax + b$.

(b) Let $V = \{ \alpha \in D : \alpha^2 \in \mathbb{R}_{\leq 0} \}$. Show that V is an \mathbb{R} -linear subspace of D. Hint: Show there is an \mathbb{R} -linear map $f: D \to \mathbb{R}$ with kernel V.

Proof. For $\alpha \in D$, define an \mathbb{R} -endomorphism T_{α} of D via left multiplication by α . This furnished a linear map $D \to \operatorname{End}_{\mathbb{R}}(D)$. We claim that V is the kernel of the composition of the \mathbb{R} -linear maps

$$D \to \operatorname{End}_{\mathbb{R}}(D) \xrightarrow{\operatorname{Tr}} \mathbb{R}.$$

Fix $\alpha \in D$ such that $\alpha \notin \mathbb{R} \cdot 1$. Then by part (a) there exist $a, b \in \mathbb{R}$ such that α satisfies a quadratic irreducible polynomial $p_{\alpha}(x) = x^2 + ax + b$. Observe that, for $v \in D$,

$$p_{\alpha}(T_{\alpha})(v) = T_{\alpha}^{2}(v) + aT_{\alpha}(v) + b(v) = \alpha^{2}v + a\alpha v + bv = (\alpha^{2} + a\alpha + b\alpha)(v) = 0$$

so $p_{\alpha}(T_{\alpha}) = 0 \in \operatorname{End}_{\mathbb{R}}(D)$. Irreducibility of p_{α} then implies that p_{α} is the minimal polynomial for the operator T_{α} . Let $\chi_{\alpha}(x)$ be the characteristic polynomial for T_{α} . Then $p_{\alpha}(x)|\chi_{\alpha}(x)$ and there exists a $k \in \mathbb{N}$ such that $\chi_{\alpha}(x)|(p_{\alpha}(x))^{k}$. As χ_{α} is monic and p_{α} is irreducible, there exists an $l \in \mathbb{N}$ such that $\chi_{\alpha}(x) = (p_{\alpha}(x))^{l}$. By multinomial expansion,

$$\chi_{\alpha}(x) = (p_{\alpha}(x))^{l} = \sum_{\substack{n_{1} + n_{2} + n_{3} = l \\ n_{1}, n_{2}, n_{3} > 0}} {l \choose n_{1}, n_{2}, n_{3}} x^{2n_{1} + n_{2}} a^{n_{2}} b^{n_{3}}$$

This polynomial has x^{2l-1} coefficient

$$\binom{l}{l-1, 1, 0}a = l \cdot a$$

However, the x^{2l-1} coefficient of χ_{α} is also $\pm \operatorname{Tr}(T_{\alpha})$, so $\pm \operatorname{Tr}(T_{\alpha}) = l \cdot a$. Moreover, as $p_{\alpha}(x)$ is irreducible, $a^2 - 4b < 0 \implies b > \frac{a^2}{4} \ge 0$. Hence, if α is such that $\operatorname{Tr}(\alpha) = 0$, then a = 0 whence $0 = p_{\alpha}(\alpha) = \alpha^2 + b \implies \alpha^2 = -b \le 0$, i.e. $\alpha \in V$. Conversely, suppose that $\alpha \in D \setminus \{0\}$ is such that $\alpha^2 < 0$. Then α is linearly independent from 1, so there exist $a, b \in \mathbb{R}$. such that $\alpha^2 + a\alpha + b = 0$. Note that, as $\alpha^2 \in \mathbb{R}$, linear independence of α from 1 implies that a = 0 and $\alpha^2 + b = 0$. Then, $\operatorname{Tr}(T_{\alpha}) = 0$, as desired.

(c) Define $B: V \times V \to \mathbb{R}$, $B(\alpha, \beta) := -\frac{\alpha\beta + \beta\alpha}{2}$. Show that B defines an inner product on V (i.e. B is a symmetric, positive definite bilinear form on V).

Proof. Observe that, for $\alpha, \beta \in V$, $\alpha^2, \beta^2, (\alpha + \beta)^2 \in \mathbb{R}$, whence $\alpha\beta + \beta\alpha = (\alpha + \beta)^2 - \alpha^2 - \beta^2 \in \mathbb{R}$, so B is in fact real-valued.

Fix $\alpha, \alpha', \beta, \beta' \in V$ and $\lambda \in \mathbb{R}$. Then

$$B(\alpha,\beta) = -\frac{\alpha\beta + \beta\alpha}{2} = -\frac{\beta\alpha + \alpha\beta}{2} = B(\beta,\alpha)$$

$$B(\alpha + \lambda\alpha',\beta) = -\frac{(\alpha + \lambda\alpha')\beta + \beta(\alpha + \lambda\alpha')}{2} = -\frac{\alpha\beta + \beta\alpha}{2} - \lambda\frac{\alpha'\beta + \beta\alpha'}{2} = B(\alpha,\beta) + \lambda B(\alpha',\beta).$$

$$B(\alpha,\beta + \lambda\beta') = -\frac{\alpha(\beta + \lambda\beta') + (\beta + \lambda\beta')\alpha}{2} = -\frac{\alpha\beta + \beta\alpha}{2} - \lambda\frac{\alpha\beta' + \beta'\alpha}{2} = B(\alpha,\beta) + \lambda B(\alpha,\beta'),$$

so B is a symmetric bilinear form. Moreover, as $\alpha \in V \setminus \{0\}$ implies that $\alpha^2 \in \mathbb{R}_{<0}$, we have then that

$$B(\alpha, \alpha) = -\frac{\alpha\alpha + \alpha\alpha}{2} = -\alpha^2 > 0$$

so B is also positive-definite.

(d) Let W be a linear subspace of V that generates D as an \mathbb{R} -algebra. Let $n = \dim_{\mathbb{R}} W$. Choose an orthonormal basis of W, i.e. a basis $\{e_i\}$ of W such that $B(e_i, e_i) = 1$ for all i and $B(e_i, e_j) = 0$ for all $i \neq j$ (such a basis always exists). Using this orthonormal basis show that if $n \geq 2$, then D has a subalgebra isomorphic to \mathbb{H} .

Proof. We must first show that such a subspace W of V with the prescribed property actually exists. Let $\psi: D \to \mathbb{R}$ denote the linear map constructed in part (b), i.e. $\psi(\alpha) = \text{Tr}(T_{\alpha})$ where T_{α} is the left multiplication by α operator. We claim that im $\psi \neq 0$, whence im $\psi = \mathbb{R}$. To show this, consider $\lambda \in R \setminus \{0\}$. With respect to any \mathbb{R} -basis of D, the matrix of T_{λ} is diagonal with nonzero entries λ along the diagonal, so $\text{Tr}(T_{\lambda}) = \lambda \dim_{\mathbb{R}} D \in \mathbb{R} \setminus \{0\}$, as desired.

By rank-nullity theorem,

$$\dim D = \dim \ker \psi + \dim \operatorname{im} \psi = \dim V + \dim \mathbb{R} = \dim V + 1$$

so dim $V = \dim D - 1$. The remaining direct summand of D is spanned by 1 and is thus \mathbb{R} , so as the subalgebra generated by V contains 1 and V, it must be all of D.

Now suppose that W is a linear subspace of V that generates D as an \mathbb{R} -algebra. Let $n = \dim_{\mathbb{R}} W$. Choose an orthonormal basis $\{e_i\}_{i=1}^n$ of W with respect to B. Then, for $i \in \{1, \ldots, n\}$,

$$1 = B(e_i, e_i) = -\frac{e_i^2 + e_i^2}{2} = -e_i^2 \implies e_i^2 = -1.$$

Also, for $i, j \in \{1, ..., n\}$,

$$0 = B(e_i, e_j) = -\frac{e_i e_j + e_j e_i}{2} \implies e_i e_j = -e_j e_i.$$

Let A be the subalgebra of D generated by $\{1, e_1, e_2\}$. We will show that $A \cong \mathbb{H}$ as \mathbb{R} -algebras.

(e) Bonus: Suppose $n \ge 2$. Prove that A = H. Hint: One way to proceed is to show that if n > 2, then the multiplication in D cannot be associative.
